File Number: 203-86059

Gentlemen:

On October 17, in a meeting with a representative of Core Laboratories, Inc., Mr. Kevin Wallace of The Anschutz Corporation, requested that Formation Resistivity Factor Measurements (at atmospheric and at overburden conditions) and Formation Resistivity Index Measurements be determined on core samples obtained from the subject well. Presented herein are final results of this investigation. Mr. Wallace received preliminary data on November 11, any revisions in the preliminary data have been made to provide more accurate interpretation of the test results.

Sample Preparation:

Four one and one-half inch diameter samples were drilled from the full diameter core material utilizing tap water as a bit coolant and lubricant. The samples were trimmed to right cylinders, then placed into a centrifuge solvent reflux apparatus, extracted of hydrocarbons and leached of salts using, respectively, cool toluene and cool methyl alcohol. Each sample was dried in a controlled-humidity oven at 140°F and 40 to 45 percent relative humidity until individual sample weights stabilized. A lithological description of each sample, as well as the depth interval from which it was obtained, is provided on Page 1. Permeability to air and Boyle's Law porosity values (using helium as the gaseous phase) were measured for each sample, with data presented in tabular format on Page 2, and in graphic format on Page 3.

Formation Resistivity Factor Measurements at Ambient and Overburden Conditions:

Samples selected for formation resistivity factor testing were testing were evacuated then pressure-saturated, as instructed by Mr. Wallace, using a sodium chloride brine having 100,000 ppm total dissolved solids. Resistance of the fully-saturated core samples was measured on successive days until the calculated resistivity of each individual sample stabilized, indicating that ionic equilibrium had been attained. Resistance was then measured at effective overburden pressures of 400 and 3680 psi. The calculated formation resistivity factors were plotted as a function of porosity from which a cementation exponent "m" was derived for each overburden pressure. All samples, with the exception of sample 33, exhibited normal trends of increasing formation resistivity factors and cementation exponents ("m") with increasing overburden pressures.

At 400 psi overburden pressure, sample 33 demonstrated a decrease in formation resistivity factor value compared to the value calculated at 0.0 psi overburden pressure. This phenomena is attributed to the coarse grains predominate in the sample causing, at atmospheric conditions, poor contacts with the source of electrical current and the sample. This poor contact, in turn, results in an erroneously high Ro measurement. Contact with the grains and source of electrical current is enhanced at 400 psi overburden pressure, resulting in an improved formation resistivity factor calculation.

Also noted in the evaluation of the cementation exponent ("m") data is sample 11. The lithological difference evident in sample 11 results in a higher "m" value than that calculated for the remaining samples of this study.

Resultant data is presented in tabular form on Page 4 and graphically on Pages 5 through 7.

Formation Resistivity Index Measurements:

Following the described formation resistivity factor testing, samples 20, 31, and 33 were partially desaturated in a capillary pressure cell with humidified air at pressures ranging from 0.5 to 35 psi. Once a significant amount of desaturation had been achieved, the resistivity was calculated for the individual samples. Due to permeability limitations, sample 20 completed the desaturation process in a high speed centrifuge with sample 11 which was desaturated using, exclusively, a high speed centrifuge at rates of rotation equivalent to pressures ranging from 300 psi to 1200 psi. After each rotation, the samples were wrapped individually in SaranTM wrap and aluminum foil and the pore fluids were allowed to redistribute for a minimum of 48 hours; the samples were then weighed and the resistance measured. The formation resistivity index calculations were plotted as a function of water saturation from which a saturation exponent "n" was determined for each The

sample. Resultant data is presented in tabular format on Page 8, and graphically on Pages 9 through 12. A composite graph is presented on Page 13.

The table below summarizes the resistivity results:

Cementation Exponent

<u>Pressure, psi</u>	<u>"a"</u>	<u>"m"</u>
0	1.00	1.84
200	1.00	1.85
3680	1.00	1.87

Saturation Exponent

<u>Sample number</u>	<u>"n"</u>
11	1.75
20	1.90
31	1.64
33	1.82
Composite	1.82

Thank you for the opportunity to perform this study for The Anschutz Corporation. Should you have any questions regarding the test results, or if we may be of further assistance, please call us at (303) 751-9334.

Sincerely yours,

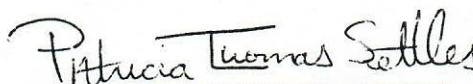

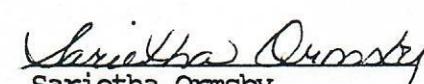

CORE LABORATORIES, INC.
